Effect of Socio-Economic Factors on Student's Performance

Jishant Acharya

25/03/2022

Introduction

School has become a place to compete against the world to prove yourself and set yourself apart from the crowd to excel. This is done to measure everyone's grasping power with the same yardstick marks. This is in no way the right manner to judge a person's intelligence. Each individual is different, everyone comes from a varied set of backgrounds. There can never be a single yardstick that can measure each and everyone. This analysis is trying to prove that.
There are various effects that have been in place in the background and have different effects on the ability of the student to perform in exams.
.
In the following exploratory analysis document we use the data set[2] and try to back the findings that were made by many researches.
We all know that there is a dependence of socio-economic parameters on marks. We will try to help back the conclusion made with respect to age that with increase in the age marks or the ability to perform goes down[3].
We also know that poverty has been an obstacle in obtaining quality education. As a domino effect , it affects the students ability to perform due to all the other circumstances that come with poverty[6].
The are various studies that back the fact that the gender of the student also plays a pivotal role in being an over-achiver, females are more likely to be over-achievers when compared to male[5].
Conclusively, we have seen in real world that there are many indirectly influencing factors that affect the marks and the overall ability to learn. There are studies that have been successful in showcasing the said effect of indirect factors on marks of the student[1].

Central Idea

The main idea is to find the factors that directly or indirectly affect the student performance.Here we will try to peg everything against the G3 value to measure performance on a single standard scale and also because G1 and G2 have a very strong correlation with G3 which shows an influence.This means if we are able to understand the influence on G3 we will easily be able to comment on the overall performance of the student.
.
We will be running a analysis that works to yield relation with with final marks for the above mentioned reasons but we also will be working in finding indirect influences by working on 2 columns that are dependent on each other which in-turn has an effect on the final marks.

Dataset Description

Variable	Type	Description
School	Categorical	One of the 2 schools in the data set
Age	Continuous	Age from 18 -22
sex	Categorical	Male or Female
schoolsup	Categorical	Yes / No for support from school
famsup	Categorical	Yes / No for support from family
Pstatus	Categorical	Living 'T' (Together) or 'A' (Apart)
G1	Continuous	Marks of first period
G2	Continuous	Marks of second period
G3	Continuous	Marks of third period

```
##    school age sex schoolsup famsup Pstatus G1 G2 G3 health
## 1      GP  18   F       yes     no       A  5  6  6      3
## 2      GP  17   F        no    yes       T  5  5  6      3
## 3      GP  15   F       yes     no       T  7  8 10      3
```

This data set has been taken from a previous research[2] that tried to predict performance of the students based on various things that influence it. It was found at various instances that there is an influence of many social and economical factors on the marks of a particular student. The data set has variables with the help of which we will try and prove the same.

Variable Description

- **School** variable is set between one of the two school of which the data is, GP moniker is given to the Gabriel Pereira School and MS tag is given to the Mousinho da Silveira School. This will help when we want to check if school has any significant influence.
- **Age** variable is a generic variable set to get context of the intelligence of the person. We have have a research that concluded that a person's ability to perform decreases with age[3]. We will use this pegged against the final score to back the research
- **Sex** this can also be a factor to predict or influence score ofa student. We know this by a previously done research that states that females are more prone to become overachievers than men[5]. This will help us put itself against G3 marks and then prove the said conclusion.
- **Schoolsup** is a categorical variable that states if the school supports the student or not. This support can also be the reason for a students score going up or down depending on the relation.
- **Famsup** is a categorical variable that states if family supports that student or not. This support and can also influence the performance.
- **PStatus** this is a categorical variable that signifies the cohabitation situation of the student and their parents.It says 'T' of they are living together and 'A' is the student is living alone.
- **G1** this is a continuous range of marks from 0-20, 0 being the lowest and 20 being perfect. This variable signifies the marks obtained in the first period.

- **G2** this is a continuous range of marks from 0-20, 0 being the lowest and 20 being perfect. This variable signifies the marks obtained in the second period.
- **G3** this is a continuous range of marks from 0-20, 0 being the lowest and 20 being perfect. This variable signifies the marks obtained in the third period.
Method

Gender Distribution

Figure 1: Population distribution between genders

```
paste("Total number of students in the sample", nrow(student.mat))
```

[1] "Total number of students in the sample 395"

```
paste("Number of Male Students: ",nrow(student.mat[student.mat$sex == 'M',]))
```

[1] "Number of Male Students: 187"

```
paste("Number of Female Students: ",nrow(student.mat[student.mat$sex == 'F',]))
```

[1] "Number of Female Students: 208"

This graph shows that there is no class bias in the dataset, the number of male is almost similar to the number of females.

Frequency Distribution of Male Population

This shows that the age of males is skewed to the left and has a tail towards the right. The Green line is the median of the distribution and the blue line is the mean of the distribution.

Frequency Distribution of Female Population

This shows that the distribution is slightly skewed to the right but not by a lot. Here also the green line shows the median and the blue line shows the mean of the distribution.
Figure 2: Male Population frequency distribution

Figure 3: Female population frequency distribution

Dependance of Sex on the Living Arrangement

To get the dependence as they both are categorical in nature, we prefer using the Chi Square Test of Independence to test the significance of one on the other.

H$_0$: *There is no significant dependence between sex and living arrangement*
H$_1$: *There is significant dependence between sex and living arrangement*

```
#Does a Chi Square Test Of Independence
chisq.test(student.mat$sex,student.mat$Pstatus)
```

```
##
##  Pearson's Chi-squared test with Yates' continuity correction
##
## data:  student.mat$sex and student.mat$Pstatus
## X-squared = 0.090428, df = 1, p-value = 0.7636
```

Here we see the P-value of the test comes out to be 0.76 which is greater than 0.05 which is the threshold value to reject the Null Hypothesis and shift to the alternate hypothesis.

Result : *We seek to determine if there is a significant dependence of sex on the living arrangement'. 395 Students from both the schools combined were used as a sample. The sample population constituted 208 female and 187 male candidates. A Chi Square Test revealed the X^2 value of 0.09, degree of freedom to be 1 and the p-value to be 0.76. This means that we reject the null hypothesis and select the alternate hypothesis that says that there is a significant dependence between the 2 metrics.*

Difference in Male & Female popoulaion with respect to marks

We will work this out using a Independant Sample T-Test as the sample space is the same but we have divided them into groups to find if gender influences marks.
Here we will use all the marks namely G1, G2 & G3 to understand if different period marks have different effect.

We will use the same hypothesis for all the three tests between the separated population.

H$_0$: *There is no difference between the marks of the corresponding periods for male and female*
H$_1$: *There is difference between the marks of the corresponding periods for male and female*

```
pulled_df <- as.data.frame(as.data.frame(student.mat)[,c("sex","G1","G2","G3")])
#Making a selective data frame
gender.groupings <- group_by(pulled_df, sex)
get_summary_stats(gender.groupings) #getting summary
```

```
## # A tibble: 6 x 14

```

Result: *We did this test to determine if gender influences any test scores. The tests were conducted for marks from all the periods that are namely G1, G2 and G3 respectively. The sample space was populated with a total of 395 students of which 208 are female and 187 are male candidates. We performed t-tests for finding if there is a difference in means of both the groups. In all the three tests pegged to the test period we found that there is a difference in the sample means for all the test periods. This test reveals that gender does influence marks irrespective of the test period in question.*

Dependance of Age on Marks (Linear Regression)

```
  #Gives the Liner Model Coefficient and Intercept
  lm(G3 ~ age, data=student.mat)
```

```
##
## Call:
## lm(formula = G3 ~ age, data = student.mat)
```
Figure 4: Age v/s G3 Regression

```
##
## Coefficients:
## (Intercept)          age
##     20.1011      -0.5801
```

Result : *The purpose of the test was to yield the relationship between age and marks of the student. The sample space was of 395 student and their final semester marks we taken into consideration. We performed linear regression on the variables and found a negative correlation. This shows that not only there is a dependence of age on marks but it's negative in nature which means as age progresses, marks of the student will come down.The estimation formula comes out to be $\hat{y} = 20.1011 - (0.5801)age$.*

Difference between the 2 schools

```
paste("Number of Students from GP school", nrow(gp_school))
```

```
## [1] "Number of Students from GP school 349"
```

```
paste("Number of Students from MS school", nrow(ms_school))
```

```
## [1] "Number of Students from MS school 46"
```

We will use the independant t-test across schools for all the evaluation periods and try to understand if school also makes a difference when it comes to marks.

H$_0$: *There is -no difference between the marks of the students from different schools of the corresponding periods*
H$_1$: *There is difference between the marks of the students from different schools of the corresponding periods*

```

##  9.847826 10.489971
```

Result: *We conducted the test to understand if they type of school has an influence on the marks that for all the periods. The sample space has 349 student from the GP school and 46 from the MS school. We ran T-Tests of independence and we found that the means are not equal. Which means that we reject the null hypothesis of equal means and understand that school has significant influence on the marks a student gets.*

Multiple Regression for Correlation

Between G1,G2 and G3 (Multiple Regression)

Mutiple regression with Intercepts and The coefficients

```
# Multiple Regression
lm(G3 ~ G1+G2, data = student.mat)
```

```
##
## Call:
## lm(formula = G3 ~ G1 + G2, data = student.mat)
##
## Coefficients:
## (Intercept)            G1            G2
##     -1.8300        0.1533        0.9869
```
Shows the linear regression of G1 and G3

Figure 5: G1 marks vs G3 Marks with Linear Regression Line

**Shows the linear regression of G2 and G3**

Figure 6: G2 marks vs G3 Marks with Liner Regression Line

Result: *We conducted test to see if there is a correlation between the G1, G2 v/s G3 marks. This would help us understand if there is a dependence on the final marks by the past marks. We did a multiple regression*

between G1, G2 and G3 to get the regression formula that will help us get the approximate relation between the said variables. $\hat{y} = -1.83 + (0.1533)G1 + (0.9869)G2$ came out to be the final multiple regression relationship.

ANOVA between Family Support, School Support and G3 marks.

Result: *We did the test in order to check if there is any influence of family and school's support on the marks of the student. We performed an Two-Way ANOVA in order to test the hypotheses. The p-values for all the relations came back positive that shows that school support and family support individually also have an influence on the student's marks. Combined family and school support yields a p-value of 0.391 which satisfies $p > 0.05$ and hence we reject the null hypothesis and understand that family and school support together have a significant influence on the final period marks. Furthermore the posthoc reveals that there is an impact of school support that influences the student's marks. It shows that there is a significance effect on marks of the student when family supports but that effect increases when the school also supports at the same time.*

Final Result

As we see from the numerous tests performed, we are able to conclude that marks cannot be the only yardstick to measure a student's intelligence and that we need to change the metric somehow.As not all have an equal footing on the world nor have all the same background.When we tried to see an what affects the score we were able to find a very strong correlation between the previous and the final period marks. Further we investigated the the effects of aging and found that with increase in age the ability to score also goes down.Additionally, when we tried to get the effects of gender on the final marks it came out that there is a significant effect of gender on the marks of the student. We further tried to find if the student's gender has any effect on the habitation and found a dependence on one another. We also could test that even the type of school a student goes to can effect the marks the student can get.

Conclusion

All this just proves the fact that a student performance isn't agnostic to socio economic factors, rather it's dependence is quite significant and if we want to alleviate a student performance we might need to work on the factors revolving students like the ones we tested to help students get there. This can help teacher and school authorities plan their teachings and also help them pave a way towards a better result posted by the student
